**Remark:** When a nondeterministic automaton with  $n$  states is transformed into a deterministic one, the resulting automaton can have  $2^n$  states.

For example when we transform an automaton with 20 states, the resulting automaton can have  $2^{20} = 1048576$  states.

It is often the case that the resulting automaton has far less than  $2^n$  states. However, the worst cases are possible.

# Generalized Nondeterministic Finite Automaton

$1 \xrightarrow{a} 3 \xrightarrow{b} 4 \xrightarrow{\epsilon} 1 \xrightarrow{a} 2 \xrightarrow{b} 5 \xrightarrow{b} 5$

# Generalized Nondeterministic Finite Automaton

Compared to a nondeterministic finite automaton, a **generalized nondeterministic finite automaton** has the so called  **$\epsilon$ -transitions**, i.e., transitions labelled with symbol  $\epsilon$ .

When  $\epsilon$ -transition is performed, only the state of the control unit is changed but the head on the tape is not moved.

**Remark:** The computations of a generalized nondeterministic automaton can be of an arbitrary length, even infinite (if the graph of the automaton contains a cycle consisting only of  $\epsilon$ -transitions) regardless of the length of the word on the tape.

# Generalized Nondeterministic Finite Automaton

Formally, a **generalized nondeterministic finite automaton** (**GNFA**) is defined as a tuple

$$(Q, \Sigma, \delta, I, F)$$

where:

- $Q$  is a finite set of **states**
- $\Sigma$  is a finite **alphabet**
- $\delta : Q \times (\Sigma \cup \{\varepsilon\}) \rightarrow \mathcal{P}(Q)$  is a **transition function**
- $I \subseteq Q$  is a set of **initial states**
- $F \subseteq Q$  is a set of **accepting states**

**Remark:** NFA can be viewed as a special case of GNFA, where  $\delta(q, \varepsilon) = \emptyset$  for all  $q \in Q$ .

# Transformation to a Deterministic Finite Automaton

A generalized nondeterministic finite automaton can be transformed into a deterministic one using a similar construction as a nondeterministic finite automaton with the difference that we add to sets of states also all states that are reachable from already added states by some sequence of  $\epsilon$ -transitions.

# Transformation of GNFA to DFA

Before formally describing the transition of GNFA to DFA, let us introduce some auxiliary definitions.

Let us assume some given GNFA  $\mathcal{A} = (Q, \Sigma, \delta, I, F)$ .

Let us define the function  $\hat{\delta} : \mathcal{P}(Q) \times (\Sigma \cup \{\varepsilon\}) \rightarrow \mathcal{P}(Q)$  so that for  $K \subseteq Q$  and  $a \in \Sigma \cup \{\varepsilon\}$  there is

$$\hat{\delta}(K, a) = \bigcup_{q \in K} \delta(q, a)$$

# Transformation of GNFA to DFA

For  $K \subseteq Q$ , let  $Cl_\varepsilon(K)$  be all the states reachable from the states from the set  $K$  by some arbitrary sequence of  $\varepsilon$ -transitions.

This means that the function  $Cl_\varepsilon : \mathcal{P}(Q) \rightarrow \mathcal{P}(Q)$  is defined so that for  $K \subseteq Q$  is  $Cl_\varepsilon(K)$  the smallest (with respect to inclusion) set satisfying the following two conditions:

- $K \subseteq Cl_\varepsilon(K)$
- For each  $q \in Cl_\varepsilon(K)$  it holds that  $\delta(q, \varepsilon) \subseteq Cl_\varepsilon(K)$ .

**Remark:** Let us note that  $Cl_\varepsilon(Cl_\varepsilon(K)) = Cl_\varepsilon(K)$  for arbitrary  $K$ .

Let us also note that in the case of NFA (where  $\delta(q, \varepsilon) = \emptyset$  for each  $q \in Q$ ) is  $Cl_\varepsilon(K) = K$ .

# Transformation of GNFA to DFA

For a given GNFA  $\mathcal{A} = (Q, \Sigma, \delta, I, F)$  we can now construct DFA  $\mathcal{A}' = (Q', \Sigma, \delta', q'_0, F')$ , where:

- $Q' = \mathcal{P}(Q)$  (so  $K \in Q'$  means that  $K \subseteq Q$ )
- $\delta' : Q' \times \Sigma \rightarrow Q'$  is defined so that for  $K \in Q'$  and  $a \in \Sigma$ :

$$\delta'(K, a) = Cl_\varepsilon(\hat{\delta}(Cl_\varepsilon(K), a))$$

- $q'_0 = Cl_\varepsilon(I)$
- $F' = \{K \in Q' \mid Cl_\varepsilon(K) \cap F \neq \emptyset\}$

It is not difficult to verify that  $\mathcal{L}(\mathcal{A}) = \mathcal{L}(\mathcal{A}')$ .

# Transformation of a Regular Expression to a Finite Automaton

## Proposition

Every language that can be represented by a regular expression is regular (i.e., it is accepted by some finite automaton).

**Proof:** It is sufficient to show how to construct for a given regular expression  $\alpha$  a finite automaton accepting the language  $\mathcal{L}(\alpha)$ .

The construction is recursive and proceeds by the structure of the expression  $\alpha$ :

- If  $\alpha$  is a elementary expression (i.e.,  $\emptyset$ ,  $\varepsilon$  or  $a$ ):
  - We construct the corresponding automaton directly.
- If  $\alpha$  is of the form  $(\beta + \gamma)$ ,  $(\beta \cdot \gamma)$  or  $(\beta^*)$ :
  - We construct automata accepting languages  $\mathcal{L}(\beta)$  and  $\mathcal{L}(\gamma)$  recursively.
  - Using these two automata, we construct the automaton accepting the language  $\mathcal{L}(\alpha)$ .

# Transformation of a Regular Expression to a Finite Automaton

**Example:** The construction of an automaton for expression  $((a + b) \cdot b)^*$ :

# Transformation of a Regular Expression to a Finite Automaton

If an expression  $\alpha$  consists of  $n$  symbols (not counting parenthesis) then the resulting automaton has:

- at most  $2n$  states,
- at most  $4n$  transitions.

**Remark:** By transforming the generalized nondeterministic automaton into a deterministic one, the number of states can grow exponentially, i.e., the resulting automaton can have up to  $2^{2n} = 4^n$  states.

# Transformation of an Automaton to a Regular Expression

## Proposition

Every regular language can be represented by some regular expression.

**Proof:** It is sufficient to show how to construct for a given finite automaton  $\mathcal{A}$  a regular expression  $\alpha$  such that  $\mathcal{L}(\alpha) = \mathcal{L}(\mathcal{A})$ .

- We modify  $\mathcal{A}$  in such a way that ensures it has exactly one initial and exactly one accepting state.
- Its states will be removed one by one.
- Its transitions will be labelled with regular expressions.
- The resulting automaton will have only two states – the initial and the accepting, and only one transition labelled with the resulting regular expression.

# Transformation of an Automaton to a Regular Expression

The main idea: If a state  $q$  is removed, for every pair of remaining states  $q_j$ ,  $q_k$  we extend the label on a transition from  $q_j$  to  $q_k$  by a regular expression representing paths from  $q_j$  to  $q_k$  going through  $q$ .

After removing of the state  $q$ :

# Transformation of an Automaton to a Regular Expression

**Example:**

# Transformation of an Automaton to a Regular Expression

**Example:**

# Transformation of an Automaton to a Regular Expression

**Example:**

# Transformation of an Automaton to a Regular Expression

## Example:

# Transformation of an Automaton to a Regular Expression

## Example:

$$\begin{aligned} & a(b + aa)^* + \\ & (b + a(b + aa)^*ab) \\ & (bb + (a + ba)(b + aa)^*ab)^* \\ & (\varepsilon + (a + ba)(b + aa)^*) \end{aligned}$$

# Equivalence of Finite Automata and Regular Expressions

## Theorem

A language is regular iff it can be represented by a regular expression.

# Nonregular Languages

Not all languages are regular.

There are languages for which there exist no finite automata accepting them.

Examples of nonregular languages:

- $L_1 = \{a^n b^n \mid n \geq 0\}$
- $L_2 = \{ww \mid w \in \{a, b\}^*\}$
- $L_3 = \{ww^R \mid w \in \{a, b\}^*\}$

**Remark:** The existence of nonregular languages is already apparent from the fact that there are only countably many (nonisomorphic) automata working over some alphabet  $\Sigma$  but there are uncountably many languages over the alphabet  $\Sigma$ .

# Nonregular Languages

How to prove that some language  $L$  is not regular?

A language is not regular if there is no automaton (i.e., it is not possible to construct an automaton) accepting the language.

But how to prove that something does not exist?

# Nonregular Languages

How to prove that some language  $L$  is not regular?

A language is not regular if there is no automaton (i.e., it is not possible to construct an automaton) accepting the language.

But how to prove that something does not exist?

**The answer:** By contradiction.

E.g., we can assume there is some automaton  $A$  accepting the language  $L$ , and show that this assumption leads to a contradiction.

# Nonregular Languages

We show that language  $L = \{a^n b^n \mid n \geq 0\}$  is not regular.

The proof by contradiction.

Let us assume there exists a DFA  $\mathcal{A} = (Q, \Sigma, \delta, q_0, F)$  such that  $\mathcal{L}(\mathcal{A}) = L$ .

# Nonregular Languages

We show that language  $L = \{a^n b^n \mid n \geq 0\}$  is not regular.

The proof by contradiction.

Let us assume there exists a DFA  $\mathcal{A} = (Q, \Sigma, \delta, q_0, F)$  such that  $\mathcal{L}(\mathcal{A}) = L$ .

Let  $|Q| = n$ .

# Nonregular Languages

We show that language  $L = \{a^n b^n \mid n \geq 0\}$  is not regular.

The proof by contradiction.

Let us assume there exists a DFA  $\mathcal{A} = (Q, \Sigma, \delta, q_0, F)$  such that  $\mathcal{L}(\mathcal{A}) = L$ .

Let  $|Q| = n$ .

Consider word  $z = a^n b^n$ .

# Nonregular Languages

We show that language  $L = \{a^n b^n \mid n \geq 0\}$  is not regular.

The proof by contradiction.

Let us assume there exists a DFA  $\mathcal{A} = (Q, \Sigma, \delta, q_0, F)$  such that  $\mathcal{L}(\mathcal{A}) = L$ .

Let  $|Q| = n$ .

Consider word  $z = a^n b^n$ .

Since  $z \in L$ , there must be an accepting computation of the automaton  $\mathcal{A}$

$$q_0 \xrightarrow{a} q_1 \xrightarrow{a} q_2 \xrightarrow{a} \cdots \xrightarrow{a} q_{n-1} \xrightarrow{a} q_n \xrightarrow{b} q_{n+1} \xrightarrow{b} \cdots \xrightarrow{b} q_{2n-1} \xrightarrow{b} q_{2n}$$

where  $q_0$  is an initial state, and  $q_{2n} \in F$ .

# Nonregular Languages

Consider now the first  $n + 1$  states of the computation

$$q_0 \xrightarrow{a} q_1 \xrightarrow{a} q_2 \xrightarrow{a} \cdots \xrightarrow{a} q_{n-1} \xrightarrow{a} q_n \xrightarrow{b} q_{n+1} \xrightarrow{b} \cdots \xrightarrow{b} q_{2n-1} \xrightarrow{b} q_{2n}$$

i.e., the sequence of states  $q_0, q_1, \dots, q_n$ .

It is obvious that all states in this sequence can not be pairwise different, since  $|Q| = n$  and the sequence has  $n + 1$  elements.

This means that there exists a state  $q \in Q$  which occurs (at least) twice in the sequence.

# Nonregular Languages

Consider now the first  $n + 1$  states of the computation

$$q_0 \xrightarrow{a} q_1 \xrightarrow{a} q_2 \xrightarrow{a} \cdots \xrightarrow{a} q_{n-1} \xrightarrow{a} q_n \xrightarrow{b} q_{n+1} \xrightarrow{b} \cdots \xrightarrow{b} q_{2n-1} \xrightarrow{b} q_{2n}$$

i.e., the sequence of states  $q_0, q_1, \dots, q_n$ .

It is obvious that all states in this sequence can not be pairwise different, since  $|Q| = n$  and the sequence has  $n + 1$  elements.

This means that there exists a state  $q \in Q$  which occurs (at least) twice in the sequence.

It is an application of so called **pigeonhole principle**.

## Pigeonhole principle

If we have  $n + 1$  pigeons in  $n$  holes then there is at least one hole containing at least two pigeons.

# Nonregular Languages

Consider now the first  $n + 1$  states of the computation

$$q_0 \xrightarrow{a} q_1 \xrightarrow{a} q_2 \xrightarrow{a} \cdots \xrightarrow{a} q_{n-1} \xrightarrow{a} q_n \xrightarrow{b} q_{n+1} \xrightarrow{b} \cdots \xrightarrow{b} q_{2n-1} \xrightarrow{b} q_{2n}$$

i.e., the sequence of states  $q_0, q_1, \dots, q_n$ .

It is obvious that all states in this sequence can not be pairwise different, since  $|Q| = n$  and the sequence has  $n + 1$  elements.

This means that there exists a state  $q \in Q$  which occurs (at least) twice in the sequence.

I.e., there are indexes  $i, j$  such that  $0 \leq i < j \leq n$  and

$$q_i = q_j$$

which means that the automaton  $\mathcal{A}$  must go through a cycle when reading the symbols  $a$  in the word  $z = a^n b^n$ .

# Nonregular Languages

The word  $z = a^n b^n$  can be divided into three parts  $u, v, w$  such that  $z = uvw$ :

$$u = a^i$$

$$v = a^{j-i}$$

$$w = a^{n-j} b^n$$

# Nonregular Languages

For the words  $u = a^i$ ,  $v = a^{j-i}$ , and  $w = a^{n-j}b^n$  we have

$$q_0 \xrightarrow{u} q_i \qquad q_i \xrightarrow{v} q_j \qquad q_j \xrightarrow{w} q_{2n}$$

Let  $r$  be the length of the word  $v$ , i.e.,  $r = j - i$  (obviously  $r > 0$ , due to  $i < j$ ).

Since  $q_i = q_j$ , the automaton accepts word  $uw = a^{n-r}b^n$  that does not belong to  $L$ :

$$q_0 \xrightarrow{u} q_i \xrightarrow{w} q_{2n}$$

The word  $uvvw = a^{n+r}b^n$ , that also does not belong to  $L$ , is accepted too:

$$q_0 \xrightarrow{u} q_i \xrightarrow{v} q_j \xrightarrow{v} q_i \xrightarrow{w} q_{2n}$$

# Nonregular Languages

Similarly we can show that every word of the form  $uvvvv \cdots vvw$ , i.e., of the form  $uv^k w$  for some  $k \geq 0$ , is accepted by the automaton  $\mathcal{A}$ :

$$q_0 \xrightarrow{u} q_i \xrightarrow{v} q_j \xrightarrow{v} q_i \xrightarrow{v} \cdots \xrightarrow{v} q_i \xrightarrow{v} q_i \xrightarrow{w} q_{2n}$$

A word of the form  $uv^k w$  looks as follows:  $a^{n-r+rk} b^n$ .

Since  $r > 0$ , the following equivalence holds only for  $k = 1$ :

$$n - r + rk = n$$

This means that if  $k \geq 1$  then  $uv^k w$  does not belong to the language  $L$ . However, the automaton  $\mathcal{A}$  accepts each such word, which is a contradiction with the assumption that  $\mathcal{L}(\mathcal{A}) = \{a^n b^n \mid n \geq 0\}$ .
